rem/L

I, **Stamoulis Litras**, dentist of Wellington affirm:

1. I am known as Stan Litras.
2. I am a self-employed dentist practising in Wellington.
3. I graduated with a BDS from Otago University in 1981. I also have a BSC in Psychology (1978) from Victoria University.
4. I have been in private practise continually since graduating from Otago. I am a member of the New Zealand Dental Association. I am a past President of the Wellington branch. I am a member of the New Zealand Academy of Cosmetic Dentistry.
5. Over the course of two science-based degrees I have had training in the scientific method and experimental methodology design (particularly under the experimental psychology papers) and have designed and participated in several (unpublished) experimental studies, including research in cariology as an assistant to Professor John C Rodda at Otago University Dental School in the late 1970s.
6. In over 30 years of practising dentistry, I have developed the skill of critically examining research in order that my practice of dentistry is evidence-based.
7. I have read, understood, and agree to comply with the Code of Conduct for expert witnesses.
8. I have read the affidavits of Gregory Simmons, John McMillan, Howard Wilkinson, Robyn Haisman-Welsh, Robin Whyman and Sandra Pryor.
9. I have been asked by the plaintiff to reply to the following points:
 - 9.1. The topical mechanism of fluoride action.
 - 9.2. A brief comment on the 2004 Lee and Dennison study and the Oral Health Survey 2010.
 - 9.3. Tooth decay rates in New Zealand..

Dan /L

- 9.4. Tooth decay rates in Taranaki.
- 9.5. Dental fluorosis.
- 9.6. Reducing oral health inequalities
- 9.7. Alternatives to water fluoridation.

Topical mechanism of action

Changing science

- 10. In the belief that higher levels of fluorine compounds in drinking water reduced decay, water fluoridation was implemented in the 1940s in USA, followed shortly thereafter by New Zealand, on the basis of two assumptions:
 - 10.1. that fluorine compounds needed to be swallowed, taken into the bloodstream and then incorporated into tooth enamel during formation; and
 - 10.2. that fluorapatite was more resistant to tooth decay than hydroxyapatite.
- 11. It was known that nutrients like iodine and calcium had to be swallowed, taken into the bloodstream, and incorporated into the human body. It was assumed that fluorine compounds worked in the same way. Tablets of sodium fluoride were even given to pregnant women in the expectation that this would strengthen the unborn child's tooth enamel in the womb.
- 12. In 1999, one of the foremost researchers in the field, J D Feathersone proved that the action of fluoride was topical, and any systemic effect was negligible or non-existent. He showed that any benefit fluoride may have occurs after teeth have erupted (come through the gum and appeared in the mouth).¹

¹ Featherstone , JDB. Prevention and reversal of dental caries: role of low level fluoride. Community dent oral Epidemiol 1999; 27: 31-40.

pwv/L

13. He concluded:

"Until recently the major caries-inhibitory effect of fluoride was thought to be due to its incorporation in tooth enamel during the development of the tooth prior to eruption. This supposed mechanism was behind public health efforts.... There is now overwhelming evidence that the primary caries-preventive mechanisms of action of fluoride are post-eruptive through 'topical' effects for both children and adults."

"The topical effects of fluoride are over-riding, and the systemic incorporation of fluoride in tooth mineral is unfortunately not a major benefit."

"[t]he concentration of fluoride in dental enamel and dentin provided by fluoridation of drinking water or by natural fluoride levels at about 1 ppm is insufficient to provide protection against caries."

"The effects are all via the [topical] mechanisms of inhibition of demineralization, enhancement of remineralization and action on bacteria."

14. Featherstone describes that the benefit from fluoride is from continued elevated levels in the saliva and plaque caused by initial application of high concentration fluoride such as in toothpaste.
15. This represented a significant shift in understanding and in my opinion calls into question the whole basis of water fluoridation.²

What is dental caries and how does fluoride work

16. Dental plaque is a colonization of microbiota which attach to the tooth enamel and each other in sequence. Some of the bacteria, notably strep. Mutans can break down sugars in the diet to form acids.

Bern /

17. The action of the acidic attack is to alter the natural equilibrium of ionic exchange between the enamel and its environment (plaque), encouraging flow of calcium out of the enamel (demineralization).
18. The dissolution of the tooth enamel and underlying dentin as a result of plaque acids is known as dental caries or tooth decay, and eventually results in cavitation.
19. The initial lesion occurs just below the surface to a depth of around a maximum of 200 microns.
20. Fluoride ions available in the saliva bind with the plaque and, under the right conditions, can flow through to the underlying enamel to encourage a reversal of ion flow into the enamel (remineralization), exchanging for hydroxyl groups and lowering solubility products of precipitating calcium phosphates encouraging the reformation of less soluble carbonates, thus slowing down the development of the lesion.
21. However, fluoride has no effect on intact enamel. It requires:
 - 21.1. That a carious lesion is already in progress.
 - 21.2. Plaque on the tooth surface is required to "bind" the fluoride in the area.
 - 21.3. Salivary fluoride concentration needs to be at least 0.03 ppm to have a remineralizing effect.³
22. It is generally well accepted now that fluorapatite is not more acid resistant than hydroxyapatite. Scandinavian researchers compared shark enamel (100% fluorapatite) with human tooth enamel and found no reduction in

Bear //

- solubility. Many studies have confirmed this.⁴
23. As fluoridated water passes fleetingly over the teeth, its topical effect will be likely to be insignificant because the concentration of 1ppm is negligible compared to other topical application modalities.⁵
 24. Rather it appears the action of fluoride to assist remineralization of early cavities in tooth enamel, which it does in bursts during the day, is related to the use of high dose topical fluoride such as toothpaste or fluoride mouth rinses , varnish and gels.⁶
 25. After brushing with toothpaste with 1000ppm fluoride, fluoride levels in saliva are elevated to the levels required to achieve a cariostatic action, and fall back to baseline levels over 2-6 hours.⁷
 26. However, as confirmed by the CDC fluoride concentration in saliva from water fluoridation is too low to provide any cariostatic effect.

⁷ Low-levels of fluoride in plaque and saliva and their effects on the demineralisation and remineralisation of enamel; role of fluoride toothpastes.: R J M Lynch, R Navada, R Walia Journal : International dental journal Date : 54-5 Suppl 1 2004.

The concentration of fluoride in ductal saliva, as it is secreted from salivary glands, is low --- approximately 0.016 parts per million (ppm) in areas where drinking water is fluoridated and 0.006 ppm in nonfluoridated areas. This concentration of fluoride is not likely to affect cariogenic activity.”⁸

- 27. Moreover, it has been shown recently that the thickness of the plaque layer together with the concentration of fluoride and the duration of exposure are vital determinants as to whether fluoride available in the saliva will have an effect in caries reduction.
- 28. Leeds university oral biologist C Robinson, showed that fluoride from saliva gets absorbed mostly in the outer layers of the dental plaque, with concentrations falling the deeper into the plaque you get. His research suggested fluoride at a concentration of 1000 ppm probably never gets to the underlying (demineralizing) enamel surface if the biofilm (the precursor to plaque) is more than approximately 500 microns (half a millimetre).⁹
- 29. It follows, therefore, that fluoride in the water would be of little benefit as a topical caries preventive agent in children who don't clean their teeth. This is because:
 - 29.1. The topical effect , at 1ppm while swallowing the water, is fleeting and at best would occur only within 15 minutes after brushing.
 - 29.2. The concentration returning in the saliva is at most 0.016ppm, well below the 0.03ppm required for remineralization.¹⁰

Stem
VV

30. In the continuum of the demineralisation-remineralisation process, the cariostatic effect of topical fluoride occurs in bursts during those times when the salivary levels of fluoride rise above 0.03ppm, (as occurs for a few hours after brushing with fluoridated toothpaste) and when the plaque thickness over the demineralizing area is small enough to allow diffusion of the Fluoride to the enamel surface.
31. Although we now understand that the beneficial effects of fluoride come from the teeth being bathed in low concentrations in saliva constantly throughout the day so that it is available at the time demineralization is occurring, researchers are referring to concentrations above 0.03ppm, and this is not available from recirculating saliva (ductal saliva) from drinking water, but from fluoride remaining in the mouth (pooled saliva) after use of high concentration topical applications like 1000ppm fluoride toothpaste.

Lee and Dennison study

32. This study is referred to by Dr Whyman and some of the defendant's other witnesses. In my opinion this study is of dubious validity because of its methodology. In particular there was no control for researcher bias, no double blinding, no standardization of recording and no verification of data. It also took no account of confounding factors such movement between fluoridated and non-fluoridated areas, use of other sources of fluoride or socioeconomic factors.
33. There are two particular aspects I wish to comment on.
34. First, the researchers used 1996 data, comparing Canterbury with Wellington. They did not identify any basis for choosing these two regions or explain why they used 1996 data. Other comparisons, for which data was also available, would have given the opposite results. For example comparing five year olds in non-fluoridated Manawatu-Whanganui (1.21 DMFT) with fluoridated Hawkes Bay (2.18 DMFT) shows 80% more decay in the fluoridated area. 12 year olds in unfluoridated Nelson-

Pen / A

- Marlborough (1.29 DMFT) had 31% less decay than fluoridated Southland (1.88).¹¹
35. Secondly, they researchers elected to use the DMFS (surfaces) scale, rather than the DMFT(teeth) which is generally used. One DMFT is equivalent to about 5 DMFS (5 tooth surfaces in each molar tooth, 4 in front teeth). Even with these manipulations, the difference they found was 1 DMFS, (2.4 compared to 1.4) or about a quarter of a filling by age.
 36. This is sometimes relied on as showing there is a 41% reduction of tooth decay ($1/2.4 \times 100$).
 37. Looking at it holistically, however, considering there are 128 tooth surfaces in a mouth, the reduction in tooth decay, can be correctly stated as $2.4 - 1.4 / 128 \times 100 = 0.78\%$.
 38. The raw data from the Ministry of Health is attached and marked "A".
 39. Graphs of the 1996 raw data for 5 year olds and 12 olds are attached and marked "B" and "C" respectively.

Our Oral Health 2010

40. This survey was undertaken for the Ministry of Health to give a "snapshot" of New Zealanders' oral health.
41. It makes several disclaimers as to the applicability of its conclusions. For example:
 - 41.1. It states: "the 2009 OHS is a sample survey at one point in time and can be used to examine associations between oral health and sociodemographic characteristics. However, readers of this report need to be aware that associations do not necessarily imply causality."
 - 41.2. And "although this survey was not designed as an in-depth water fluoridation study, data were examined...."

¹¹ Ministry of Health, oral health data 1996.

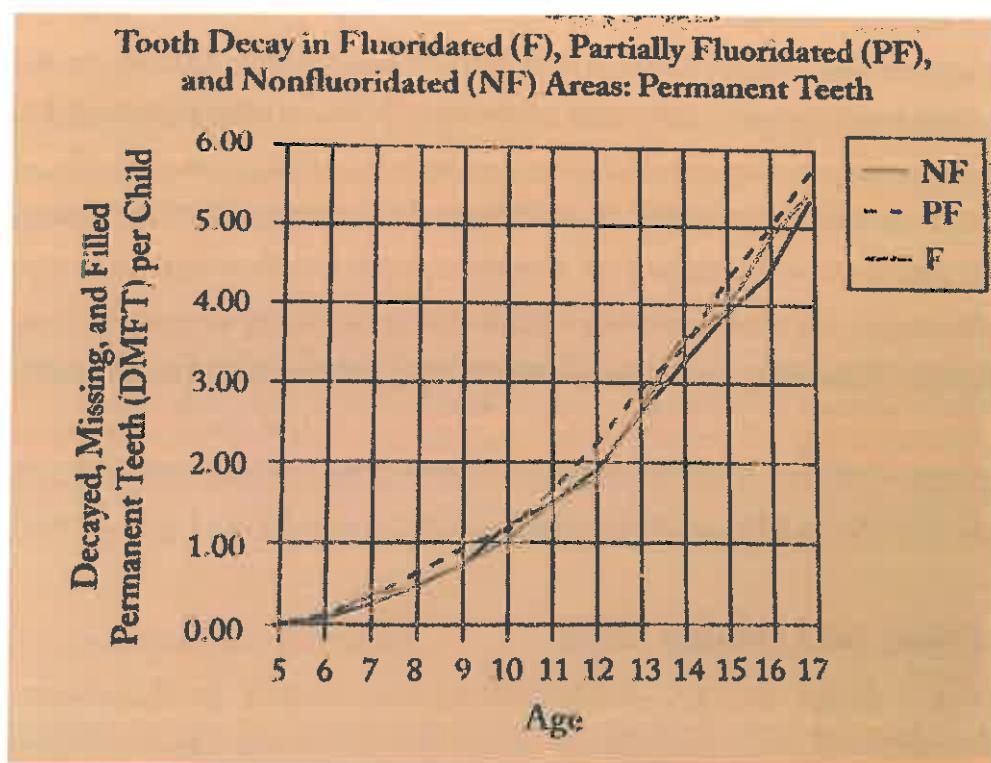

42. In my opinion the accuracy of the data is poor, with anomalies in sample size numbers making any data null and void. An errata was published in March 2011: “there has been a revision to chapter 3: Methods, page 36. It should read: a total of 3196 New Zealanders were dentally examined, including 2209 adults aged 18 years and over and 987 children and adolescents aged 2-17 years. Among adults, 781 Maori, 219 Pacific, 380 Asian and 1353 European/other adults were dentally examined. Among children and adolescents aged 2-17 years, there were 461 Maori, 184 Pacific, 171 Asian and 570 European/other children and adolescents dentally examined.”
43. These figures also appear in the data Table C2 the end of the book. The validity of the data is in question when the sample size, even after errata correction, is still out by around 40%.
44. This is demonstrated by the table C2 which says that a total of 987 children were examined. But the individual ethnic numbers add up to 1386, not 987. Individuals could only select one ethnicity.
45. And Table C3 identifies a total number of 2209 adults comprising f 781 plus 219 plus 380 plus 1353. However the total number based on the individual figures is actually 2733.
46. In my opinion this throws the figures and conclusions into question.
47. Assuming the age group data are accurate, the number of children actually examined in the 5 to 11 year age group (438) was evenly proportioned, then that would mean that less than 100 children per age group year in that age range would have been examined (ie 438 divided by 6).
48. It is very difficult to draw conclusions based on such small sample sizes.
49. A copy of Tables C2 and C3 are attached and marked “D”.

Tooth decay rates in New Zealand overall and in Taranaki in particular

50. The York Report 2000, undertaken for the UK MOH, was the biggest study of fluoride research to that time. They found of all research papers

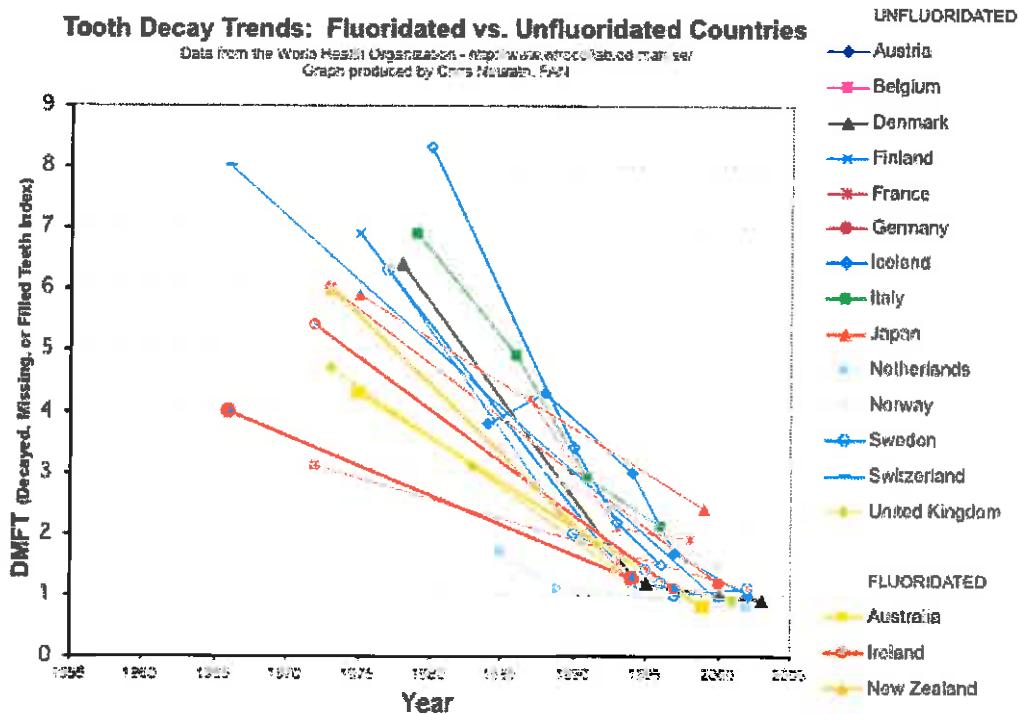

from 1945 until January 2000, in any language, only 214 were of a minimal adequate scientific quality to take into consideration. Most were of very poor methodology, in not allowing for confounding factors or researcher bias for example. They considered at that time the weight of evidence suggested an increase in percent caries-free children in fluoridated communities of under 15%.

51. In 1986 the National Institute of Dental Research in the largest US study of its kind, examined 39,000 schoolchildren in 84 communities USA. The difference in 5-17 year olds in DMFS (surfaces) was a negligible 0.6 of a tooth surface (out of around 140 surfaces). After correcting calculations errors by the original researchers, Yiammounyianis showed the decay rates in fluoridated, non-fluoridated, and partially fluoridated communities were identical.¹²

¹² Yiammounyianis JA, Water Fluoridation and Tooth Decay: results from the 1986 -87 national survey of US school children, Fluoride 23, 2 (1990) 55- 67.

Ben
//

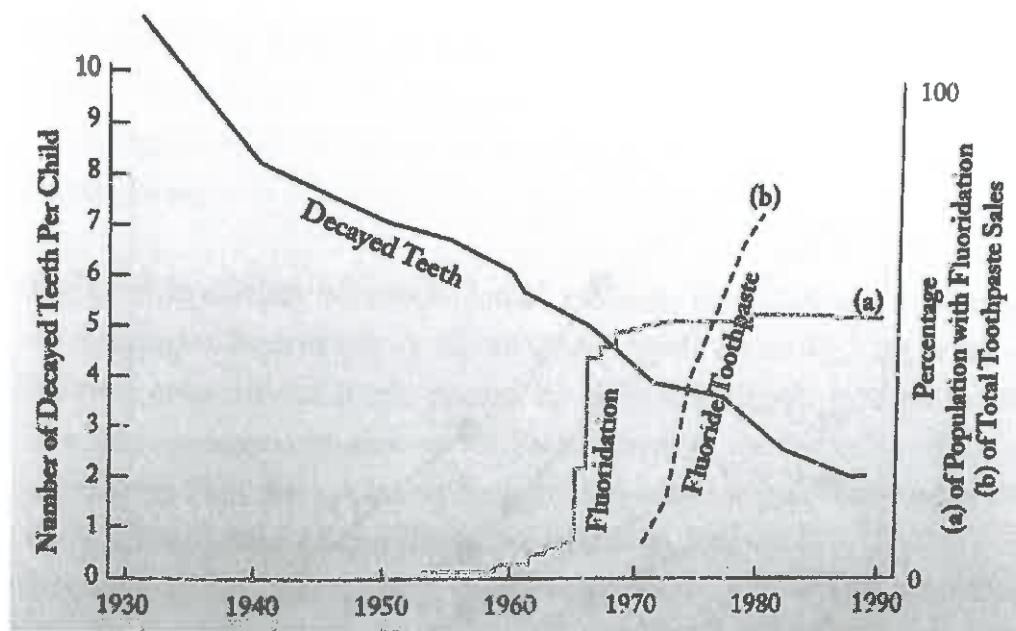

52. WHO data (2012) above show no differences between fluoridated and non fluoridated communities.¹³
53. New Zealand data is recorded by the school dental service each year, the last figures available from 2011. It recorded data from around 45,000 5 year olds and 45,000 12 year olds and is available on the Ministry of Health website under the Oral Health section.
54. Tooth decay was falling in New Zealand at the same rate even before fluoridation was in widespread use as shown by the graph below.¹⁴

¹³ WHO collaborating centre for Education, Training and Research in Oral Health, Malmö University, Sweden <http://www.mah.se/CAPP/>.

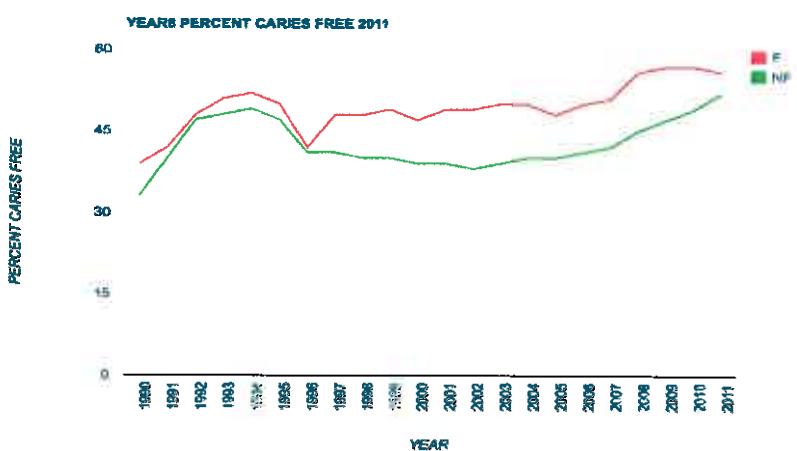

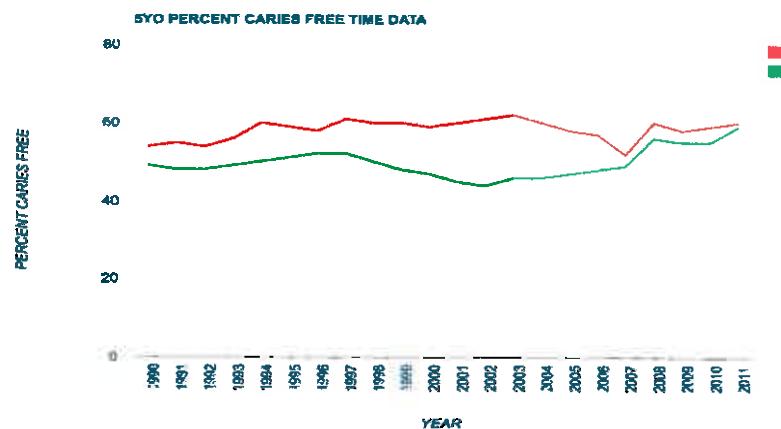

¹⁴ Colquhoun J, (1984) new evidence on fluoridation. Social science and Medicine 19: 1239-1246. de Liefde B, (1998), the decline of caries in New Zealand over the past 40 years. NZDJ, 94: 109-113.

Pen/PL

55. Currently, the average caries rate in 12 years olds in New Zealand is less than 2 DMFT out of 24 to 28 teeth. Reducing DMFT by even 30% still is only less than one filling.
56. In my opinion this is hardly a major benefit conferred by water fluoridation.
57. Treatment by filling takes approximately 15 minutes and is painless with the use of local anaesthetic.
58. In my experience the quality of life of a child with 1 or 2 or even 5 to 10 fillings is not affected by the number of fillings per se.
59. Based on the Ministry of Health's 2011 figures, the percentage of caries free 5 year olds in fluoridated areas is 59.91% (population 25,849) and in non-fluoridated areas 59.18% (18,804).
60. For year 8 children the figures are 55.17% caries free in fluoridated areas compared with 51.79% in non-fluoridated areas.
61. A copy of the Ministry of Health's 2011 figures for 5 and 12 years olds is attached and marked "E".

Perry
11

62. I have also prepared the time series graphs above for 5 and 12 year olds from the website data.
63. Using the figures in Appendix E for 5 year olds shows that there are non fluoridated areas that have lower decay rates than fluoridated areas, and vice versa. However, overall the differences are insignificant.
64. For example, looking at populations with similar numbers of fluoridated and nonfluoridated children such as Waikato show 64.12 % of children are

Benz /L

- caries free in non-fluoridated areas compared with 57.60% in fluoridated areas.
65. Southern DHB also has similar numbers in fluoridated and non-fluoridated areas. 69.48 % of children are caries free in non-fluoridated areas compared with 71.17% in fluoridated areas.
 66. In the data for Taranaki, there little difference between fluoridated and non- fluoridated communities.
 67. Although Maori and Pacific Islanders generally appear to have higher decay rates than European in these figures, there are ethnic differences in maturity and tooth eruption which are not allowed for. Teeth in these ethnic groups are often in the mouth, so exposed to plaque acids, for up to a year and a half longer than the teeth of Europeans of the same age.¹⁵
 68. It has also been shown that tooth eruption is delayed in fluoridated communities by up to 9 months.¹⁶
 69. When the differences in eruption times between different ethnicities, and between fluoridated and non fluoridated communities is taken into account, any small apparent benefits to the decay rate are nullified.
 70. Finally, to my knowledge there has not, to date, been any reliable research evidence to show that water fluoridation provides any statistically or clinically significant oral health benefit to adults.¹⁷

Fluorosis

71. Fluoride ingestion systemically during tooth development can cause porosities in the enamel, known as dental fluorosis, which manifest as chalky patches (classified as mild), white and dark brown discolourations (moderate), and pitting and malformation of the enamel (severe).
72. This occurs because fluoride ions interfere with the normal function of the ameloblasts (enamel forming cells), generally during 10-20 months of age, when enamel formation is taking place.

73. Fluorosis is not the result of topical application of fluoride post eruption. This photo was taken last month of a new patient to my Wellington practice, in his thirties and having lived his whole life in fluoridated (0.7 ppm) Lower Hutt. This patient, like other patients I have treated for this condition has had self esteem issues and difficulties socialising. His wife asked him to visit me. The cost of correction in such cases is around \$1,100 per tooth. In my experience, patients undergoing such treatments do not consider that water fluoridation has saved them money, pain or suffering

BM / 12

74. This would be classified as “moderate fluorosis” (white and brown stains in the enamel). I would see about 2-3 people a month in my private practice with this situation. I would estimate that of people who have spent their childhood lives drinking fluoridated water, 5-10% would be this severe.
75. I see patients with mild fluorosis several times a day, and have not met any who think it enhances the aesthetics of their teeth.

Health inequalities and alternatives to fluoridation

76. It is my opinion that even assuming water fluoridation reduces decay by 15%, it is of little if any benefit in reducing decay for people who don't clean their teeth and have a poor diet. If plaque is not removed from the teeth, any topical effect from fluoride in the water will be of limited benefit.
77. Tooth decay is caused by sugars in the diet (soft drinks, fast food) and lack of oral hygiene, not by fluoride deficiency.
78. Further, no amount of fluoridated water is going to prevent conditions like the nursing bottle syndrome pictured below. This condition is caused by parents leaving babies to suck on bottles filled with sugar drinks. Water fluoridation does not stop this from occurring. Any suggest fluoridation can overcome this amount of caries activity shows poor knowledge of the processes discussed above, with a mistaken belief that teeth become hardened against acids from incorporation of fluorides during development.

79. In my opinion more effective, targeted preventive policies would include: banning soft drinks and sugary snacks in schools, fluoridated salt in fast foods and soft drinks in at risk areas, supervised tooth brushing programmes in schools, diet and oral hygiene education for low socio-economic families, and improved access to dental care. Such an approach may have spin -offs in prevention of growing endemic diseases in our society such as diabetes and obesity, which obviously share some causality factors. This approach is consistent with the UK National Health Service's "Childsmile" programme in Scotland.¹⁸
80. In addition, for those at high risk of dental caries I would recommend fluoride mouth rinses, and professionally applied gels and foams..
